

## Lab Guide

# LIDAR Point Cloud

## Content Description

The following document describes a point cloud implementation in either python or MATLAB software environments utilizing the virtual QCar.

| Running the Example | 5 |
| Details             | 5 |

Prior to starting the example please go to the **Cityscape Lite** workspace and run the **qlabs\_setup\_applications.py** python script to configure the virtual world.

## MATLAB

In this example, we will capture LIDAR data from the RP LIDAR A2 on the Virtual QCar, send the data to a polar plot, and generate a point cloud map. The process is shown in Figure 1.

Figure 1. Component diagram

In addition, a timing module will be monitoring the entire application's performance. The Simulink implementation is displayed in Figure 2 below.

Figure 2. Simulink implementation of Lidar Point Cloud

## Running the example

To run examples for virtual QCar please go to the **SIMULATION** tab in the ribbon interface and click on the Run icon.

As your environment size may vary, change the maximumDistance (m) parameter within the pointCloud subsystem accordingly, up to a maximum of 4m (corresponding to an 8 x 8 m room). Figure 3 shows the typical output expected when running this example.

## Details

### 1. Capturing LIDAR data

The RP LIDAR A2 reads data in a clockwise manner, starting from a position opposite to the data cable attached to it. On the QCar platform, this corresponds to the +y axis. To correct this, the

**captureLIDAR** subsystem corrects the order of the data to start at the front and orient counterclockwise to follow standard convention in the **bodyFrameAdjustmentOnCapture** function.

### 2. Saturating the distances data meaningfully

To limit the scope of the data to a range, the **distances** data is dynamically saturated using the **maximumDistance** parameter. The **findXYContour** function then converts the **distance/heading** data pairs to **X Y** pairs. However, we would like the **X Y** points corresponding to the **maximumDistance** to not show up within the point cloud itself, as they simply correspond to a maximum range and not physical obstacles. To do so, the **findXYContour** also drops data points that are equal to the **maximumDistance**

To improve performance, we only create a blank map on the first call by the use of persistent MATLAB variables. The variable `map_internal` holds its value at any given iteration into the next call. At the end of the function, the `mapOut` is updated and then displayed.

## Python

In this example, we will capture LIDAR data from the RP LIDAR A2 on the virtual QCar, and generate a point cloud map. The process is shown in Figure 4.

Figure 4. Component diagram

### Running the Example

Check [User Manual – Software Python](#) for details on deploying python applications. Run the **lidar\_point\_cloud.py** example on your local machine. As your room size may vary, change the parameters **dim** and **gain** as you see fit. Figure 5 shows the typical output expected when running this example (via XLaunch).

### Details

#### Capturing LIDAR data

Using the `pal.products.qcar` module we import the `QCarLidar` class which configures the communication protocols for collecting data from the virtual QCar. We can specify the number of points using the **numMeasurements** variable.

```
# LIDAR initialization and measurement buffers
myLidar = QCarLidar(numMeasurements=numMeasurements)

# To read the LiDAR
myLidar.read()
```

## 2. Converting distances/angles to x y

After heading angles are converted from lidar frame to QCar body frame, the **distance/heading** data pairs are converted to **x y** pairs (in meters) using the lines below, and then to **pX pY** pairs (in pixels) for the image.

```
x = myLidar.distances[idx]*np.cos(anglesInBodyFrame[idx])
y = myLidar.distances[idx]*np.sin(anglesInBodyFrame[idx])

pX = (sideLengthScale/2 - x*pixelsPerMeter).astype(np.uint16)
pY = (sideLengthScale/2 - y*pixelsPerMeter).astype(np.uint16)
```

## 3. Generating the point cloud

Note that the **map** is set to zeros at the beginning.

```
map = np.zeros((dim, dim), dtype=np.float32)
```

It is then decayed slowly using the **decay** parameter at the start of the loop.

```
map = decay*map
```

A line below updates the **map** at the locations **pX pY** near the end of the loop.

```
map[pX, pY] = 1
```

## 4. Performance considerations

To improve performance, we only create a blank map when initializing the code. Within the main loop, older map data is slowly decayed. The module **opencv** provides the **waitKey()** method for pausing in this case. See [User Manual – Software Python](#) for more information on timing.
